#### Advanced Data Structures

# Search, index construction and compression

Slides modified from Hinrich Schütze and Christina Lioma slides

#### Inverted Index

For each term t, we store a list of all documents that contain t.

:

dictionary

postings

#### Inverted index construction

Collect the documents to be indexed:

Friends, Romans, countrymen. So let it be with Caesar . . .

2 Tokenize the text, turning each document into a list of tokens:

Friends Romans countrymen So . . .

3 Do linguistic preprocessing, producing a list of normalized tokens, which are the indexing terms: friend roman

countryman so . . .

4 Index the documents that each term occurs in by creating an inverted index, consisting of a dictionary and postings.

## Tokenizing and preprocessing

Doc 1. I did enact Julius Caesar: I was killed i' the Capitol; Brutus killed me.

**Doc 2.** So let it be with Caesar. The noble Brutus hath told you Caesar was ambitious:

Doc 1. i did enact julius caesar i was killed i' the capitol brutus killed me Doc 2. so let it be with caesar the noble brutus hath told you caesar was ambitious

## Generate posting

Doc 1. i did enact julius caesar i was killed i' the capitol brutus killed me
Doc 2. so let it be with caesar the noble brutus hath told you caesar was ambitious

|           | - |
|-----------|---|
| did       | 1 |
| enact     | 1 |
| julius    | 1 |
| caesar    | 1 |
| i         | 1 |
| was       | 1 |
| killed    | 1 |
| i"        | 1 |
| the       | 1 |
| capitol   | 1 |

#### Create postings lists, determine document frequency

## Split the result into dictionary and postings file

## Simple conjunctive query (two terms)

- Consider the query: BRUTUS AND CALPURNIA
- To find all matching documents using inverted index:
  - 1 Locate BRUTUS in the dictionary
  - Retrieve its postings list from the postings file
  - 3 Locate CALPURNIA in the dictionary
  - 4 Retrieve its postings list from the postings file
  - Intersect the two postings lists
  - 6 Return intersection to user

## Intersecting two posting lists

Brutus 
$$\longrightarrow$$
 1  $\longrightarrow$  2  $\longrightarrow$  4  $\longrightarrow$  11  $\longrightarrow$  31  $\longrightarrow$  45  $\longrightarrow$  174 Calpurnia  $\longrightarrow$  2  $\longrightarrow$  31  $\longrightarrow$  54  $\longrightarrow$  101 Intersection  $\Longrightarrow$  2  $\longrightarrow$  31

- This is linear in the length of the postings lists.
- Note: This only works if postings lists are sorted.

## Intersecting two posting lists

```
INTERSECT(p_1, p_2)
      answer \leftarrow \langle \ \rangle
  2 while p_1 \neq \text{NIL} and p_2 \neq \text{NIL}
       do if docID(p_1) = docID(p_2)
  3
              then ADD(answer, docID(p_1))
                      p_1 \leftarrow next(p_1)
  5
                      p_2 \leftarrow next(p_2)
  6
              else if docID(p_1) < docID(p_2)
                         then p_1 \leftarrow next(p_1)
  8
                         else p_2 \leftarrow next(p_2)
  9
 10
       return answer
```

#### Typical query optimization

- Example query: BRUTUS AND CALPURNIA AND CAESAR
- Simple and effective optimization: Process in order of increasing frequency
- Start with the shortest postings list, then keep cutting further
- In this example, first CAESAR, then CALPURNIA, then BRUTUS

Brutus 
$$\longrightarrow$$
 1  $\longrightarrow$  2  $\longrightarrow$  4  $\longrightarrow$  11  $\longrightarrow$  31  $\longrightarrow$  45  $\longrightarrow$  174 Calpurnia  $\longrightarrow$  2  $\longrightarrow$  31  $\longrightarrow$  54  $\longrightarrow$  101 Caesar  $\longrightarrow$  5  $\longrightarrow$  31

# Optimized intersection algorithm for conjunctive queries

```
INTERSECT(\langle t_1, \dots, t_n \rangle)

1   terms \leftarrow SORTBYINCREASINGFREQUENCY(\langle t_1, \dots, t_n \rangle)

2   result \leftarrow postings(first(terms))

3   terms \leftarrow rest(terms)

4   while terms \neq NIL and result \neq NIL

5   do result \leftarrow INTERSECT(result, postings(first(terms)))

6   terms \leftarrow rest(terms)

7   return result
```

## Recall basic intersection algorithm

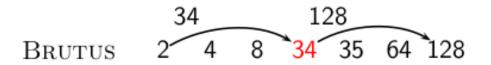

Brutus 
$$\longrightarrow$$
 1  $\longrightarrow$  2  $\longrightarrow$  4  $\longrightarrow$  11  $\longrightarrow$  31  $\longrightarrow$  45  $\longrightarrow$  174 Calpurnia  $\longrightarrow$  2  $\longrightarrow$  31  $\longrightarrow$  54  $\longrightarrow$  101 Intersection  $\Longrightarrow$  2  $\longrightarrow$  31

- Linear in the length of the postings lists.
- Can we do better?

#### Skip pointers

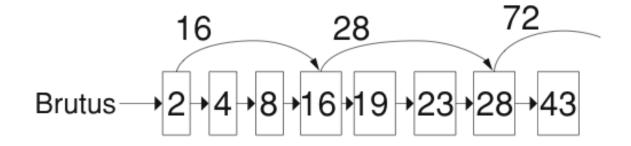

- Skip pointers allow us to skip postings that will not figure in the search results.
- This makes intersecting postings lists more efficient.
- Some postings lists contain several million entries so efficiency can be an issue even if basic intersection is linear.
- Where do we put skip pointers?
- How do we make sure intersection results are correct?

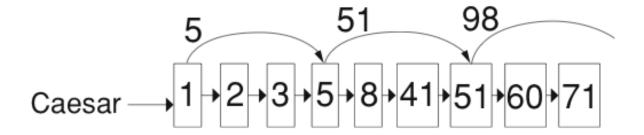

#### Basic idea

## Skip lists: Larger example

## Intersection with skip pointers

```
IntersectWithSkips(p_1, p_2)
      answer \leftarrow \langle \ \rangle
      while p_1 \neq \text{NIL} and p_2 \neq \text{NIL}
  3
      do if docID(p_1) = docID(p_2)
             then Add (answer, doclD(p_1))
  4
  5
                    p_1 \leftarrow next(p_1)
                    p_2 \leftarrow next(p_2)
  6
  7
             else if doclD(p_1) < doclD(p_2)
  8
                       then if hasSkip(p_1) and (docID(skip(p_1)) \leq docID(p_2))
  9
                                then while hasSkip(p_1) and (docID(skip(p_1)) \leq docID(p_2))
 10
                                       do p_1 \leftarrow skip(p_1)
                                else p_1 \leftarrow next(p_1)
 11
 12
                       else if hasSkip(p_2) and (docID(skip(p_2)) \leq docID(p_1))
                                then while hasSkip(p_2) and (docID(skip(p_2)) \leq docID(p_1))
 13
14
                                       do p_2 \leftarrow skip(p_2)
15
                                else p_2 \leftarrow next(p_2)
 16
      return answer
```

#### Where do we place skips?

- Tradeoff: number of items skipped vs. frequency skip can be taken
- More skips: Each skip pointer skips only a few items, but we can frequently use it.
- Fewer skips: Each skip pointer skips many items, but we can not use it very often.

#### Phrase queries

- We want to answer a query such as [stanford university] as a phrase.
- Thus The inventor Stanford Ovshinsky never went to university should not be a match.
- The concept of phrase query has proven easily understood by users.
- About 10% of web queries are phrase queries.
- Consequence for inverted index: it no longer suffices to store docIDs in postings lists.
- Two ways of extending the inverted index:
  - biword index
  - positional index

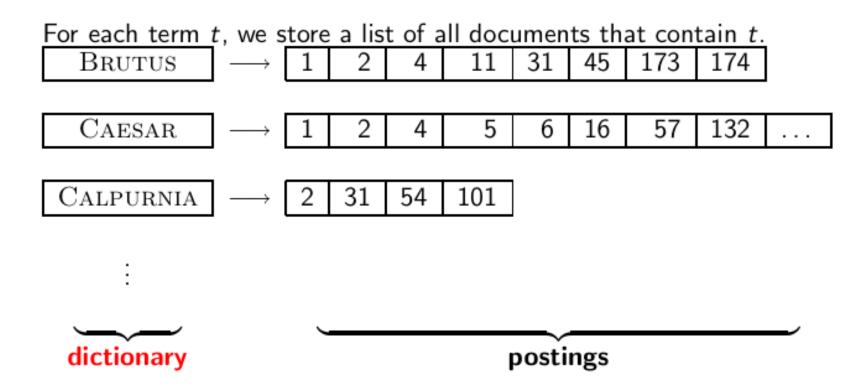

#### Positional indexes

- Postings lists in a nonpositional index: each posting is just a docID
- Postings lists in a positional index: each posting is a docID and a list of positions

## Positional indexes: Example

```
Query: "to_1 be<sub>2</sub> or<sub>3</sub> not<sub>4</sub> to<sub>5</sub> be<sub>6</sub>"
то, 993427:
    < 1: <7, 18, 33, 72, 86, 231>;
      2: <1, 17, 74, 222, 255>;
      4: (8, 16, 190, 429, 433);
      5: <363, 367);
      7: (13, 23, 191); . . . >
BE, 178239:
    1: <17, 25>;
      4: (17, 191, 291, 430, 434);
      5: <14, 19, 101>; . . . > Document 4 is a match!
```

#### Inverted index

#### **Dictionaries**

- The dictionary is the data structure for storing the term vocabulary.
- Term vocabulary: the data
- Dictionary: the data structure for storing the term vocabulary

#### Dictionary as array of fixed-width entries

- For each term, we need to store a couple of items:
  - document frequency
  - pointer to postings list
  - . . .
- Assume for the time being that we can store this information in a fixed-length entry.
- Assume that we store these entries in an array.

## Dictionary as array of fixed-width entries

| term   | document  | pointer to        |
|--------|-----------|-------------------|
|        | frequency | postings list     |
| a      | 656,265   | $\longrightarrow$ |
| aachen | 65        | $\longrightarrow$ |
|        |           |                   |
| zulu   | 221       | $\longrightarrow$ |

space needed: 20 bytes 4 bytes 4 bytes

How do we look up a query term  $q_i$  in this array at query time? That is: which data structure do we use to locate the entry (row) in the array where  $q_i$  is stored?

#### Data structures for looking up term

- Two main classes of data structures: hashes and trees
- Some IR systems use hashes, some use trees.
- Criteria for when to use hashes vs. trees:
  - Is there a fixed number of terms or will it keep growing?
  - What are the relative frequencies with which various keys will be accessed?
  - How many terms are we likely to have?

#### Hashes

- Each vocabulary term is hashed into an integer.
- Try to avoid collisions
- At query time, do the following: hash query term, resolve collisions, locate entry in fixed-width array
- Pros: Lookup in a hash is faster than lookup in a tree.
  - Lookup time is constant.
- Cons
  - no way to find minor variants (resume vs. résumé)
  - no prefix search (all terms starting with automat)
  - need to rehash everything periodically if vocabulary keeps growing

#### **Trees**

- Trees solve the prefix problem (find all terms starting with automat).
- Simplest tree: binary tree
- Search is slightly slower than in hashes: O(logM), where M is the size of the vocabulary.
- O(logM) only holds for balanced trees.
- Rebalancing binary trees is expensive.
- B-trees mitigate the rebalancing problem.
- B-tree definition: every internal node has a number of children in the interval [a, b] where a, b are appropriate positive integers, e.g., [2, 4].

#### Sort-based index construction

- As we build index, we parse docs one at a time.
- The final postings for any term are incomplete until the end.
- Can we keep all postings in memory and then do the sort inmemory at the end?
- No, not for large collections
- At 10–12 bytes per postings entry, we need a lot of space for large collections.
- But in-memory index construction does not scale for large collections.
- Thus: We need to store intermediate results on disk.

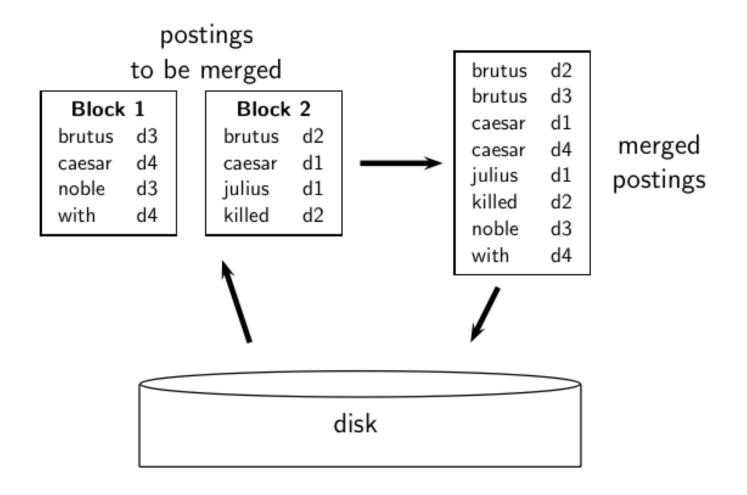

## Same algorithm for disk?

- Can we use the same index construction algorithm for larger collections, but by using disk instead of memory?
- No: Sorting for example 100,000,000 records on disk is too slow – too many disk seeks.
- We need an external sorting algorithm.

# "External" sorting algorithm (using few disk seeks)

- We must sort 100,000,000 non-positional postings.
  - Each posting has size 12 bytes (4+4+4: termID, docID, document frequency).
- Define a block to consist of 10,000,000 such postings
  - We can easily fit that many postings into memory.
  - We will have 10 such blocks.
- Basic idea of algorithm:
  - For each block: (i) accumulate postings, (ii) sort in memory, (iii) write to disk
  - Then merge the blocks into one long sorted order.

## Merging two blocks

#### **Blocked Sort-Based Indexing**

```
BSBINDEXCONSTRUCTION()

1  n ← 0

2  while (all documents have not been processed)

3  do n ← n + 1

4   block ← PARSENEXTBLOCK()

5   BSBI-INVERT(block)

6   WRITEBLOCKTODISK(block, f<sub>n</sub>)

7  MERGEBLOCKS(f<sub>1</sub>,..., f<sub>n</sub>; f<sub>merged</sub>)
```

## Problem with sort-based algorithm

- Our assumption was: we can keep the dictionary in memory.
- We need the dictionary (which grows dynamically) in order to implement a term to termID mapping.
- Actually, we could work with term, docID postings instead of termID, docID postings . . .
- . . . but then intermediate files become very large. (We would end up with a scalable, but very slow index construction method.)

## Single-pass in-memory indexing

- Abbreviation: SPIMI
- Key idea 1: Generate separate dictionaries for each block no need to maintain term-termID mapping across blocks.
- Key idea 2: Don't sort. Accumulate postings in postings lists as they occur.
- With these two ideas we can generate a complete inverted index for each block.
- These separate indexes can then be merged into one big index.

#### SPIMI-Invert

```
SPIMI-INVERT(token_stream)
     output\_file \leftarrow NewFile()
    dictionary \leftarrow NewHash()
     while (free memory available)
     do token ← next(token_stream)
         if term(token) ∉ dictionary
  5
 6
           then postings_list ← ADDTODICTIONARY(dictionary,term(token))
           else postings\_list \leftarrow GetPostingsList(dictionary, term(token))
 8
         if full(postings_list)
           then postings\_list \leftarrow DoublePostingsList(dictionary, term(token))
 10
         AddToPostingsList(postings_list,doclD(token))
     sorted\_terms \leftarrow SortTerms(dictionary)
 11
     WriteBlockToDisk(sorted\_terms, dictionary, output\_file)
 12
 13
     return output_file
Merging of blocks is analogous to BSBI.
```

## Why compression in information retrieval?

- First, we will consider space for dictionary
  - Main motivation for dictionary compression: make it small enough to keep in main memory
- Then for the postings file
  - Motivation: reduce disk space needed, decrease time needed to read from disk
  - Note: Large search engines keep significant part of postings in memory
- We will devise various compression schemes for dictionary and postings.

## Dictionary compression

- The dictionary is small compared to the postings file.
- But we want to keep it in memory.
- Also: competition with other applications, cell phones, onboard computers, fast startup time
- So compressing the dictionary is important.

## Recall: Dictionary as array of fixed-width entries

| term   | document  | pointer to        |  |  |
|--------|-----------|-------------------|--|--|
|        | frequency | postings list     |  |  |
| a      | 656,265   | $\longrightarrow$ |  |  |
| aachen | 65        | $\longrightarrow$ |  |  |
|        |           |                   |  |  |
| zulu   | 221       | $\longrightarrow$ |  |  |

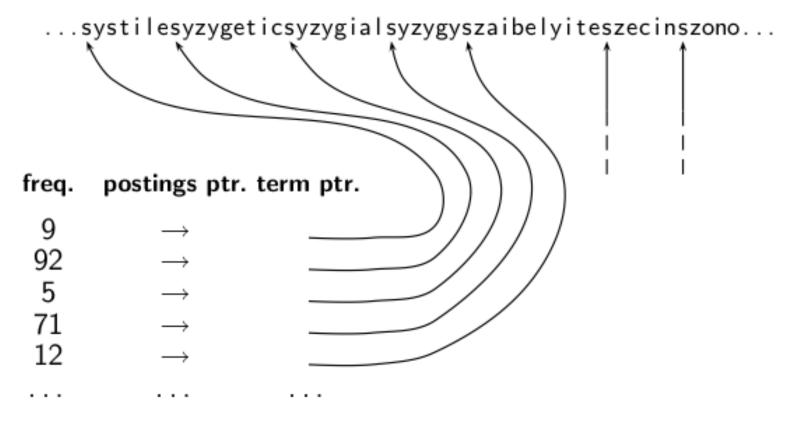

Space needed: 20 bytes 4 bytes 4 bytes

for Reuters: (20+4+4)\*400,000 = 11.2 MB

#### Fixed-width entries are bad.

- Most of the bytes in the term column are wasted.
  - We allot 20 bytes for terms of length 1.
- We can't handle HYDROCHLOROFLUOROCARBONS and SUPERCALIFRAGILISTICEXPIALIDOCIOUS
- Average length of a term in English: 8 characters
- How can we use on average 8 characters per term?

## Dictionary as a string

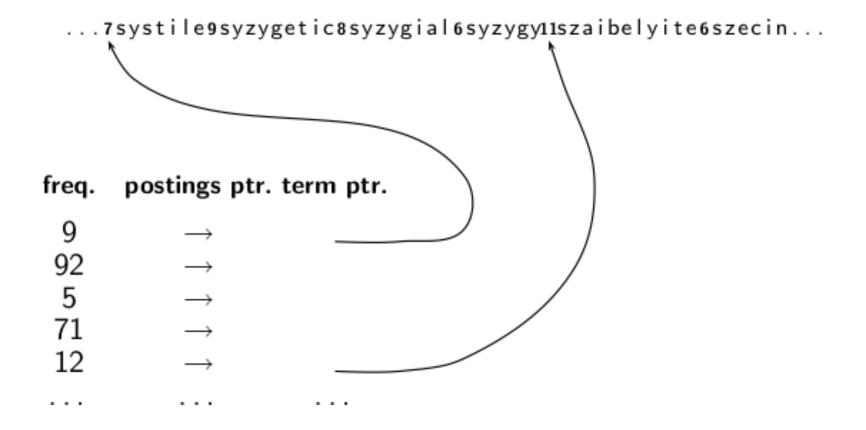

4 bytes 4 bytes 3 bytes

## Space for dictionary as a string

- 4 bytes per term for frequency
- 4 bytes per term for pointer to postings list
- 8 bytes (on average) for term in string
- 3 bytes per pointer into string (need log<sub>2</sub> 8 · 400000 < 24 bits to resolve 8 · 400,000 positions)</li>
- Space:  $400,000 \times (4 + 4 + 3 + 8) = 7.6MB$  (compared to 11.2 MB for fixed-width array)

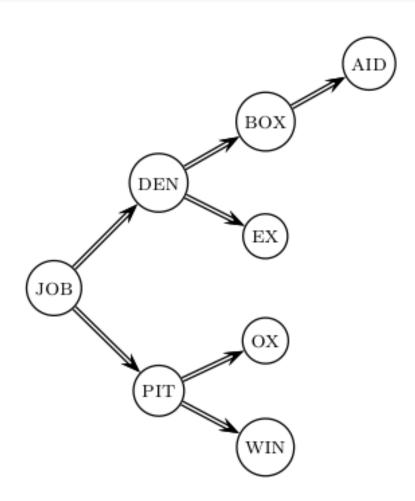

## Dictionary as a string with blocking

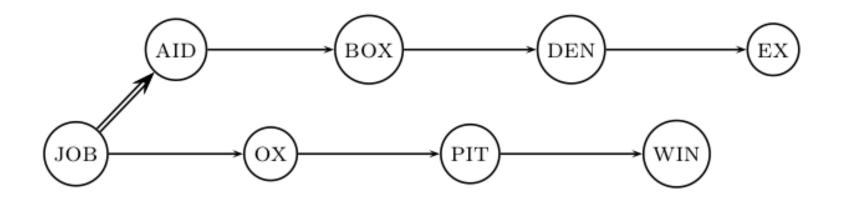

## Space for dictionary as a string with blocking

- Example block size k = 4
- Where we used 4 × 3 bytes for term pointers without blocking . . .
- . . .we now use 3 bytes for one pointer plus 4 bytes for indicating the length of each term.
- We save 12 (3 + 4) = 5 bytes per block.
- Total savings: 400,000/4 \* 5 = 0.5 MB
- This reduces the size of the dictionary from 7.6 MB to 7.1 MB.

# Lookup of a term without blocking

## Lookup of a term with blocking: (slightly) slower

## Front coding

```
One block in blocked compression (k = 4) \dots
8 a u t o m a t a 8 a u t o m a t e 9 a u t o m a t i c 10 a u t o m a t i o n

... further compressed with front coding.
8 a u t o m a t * a 1 \( \) e 2 \( \) i c 3 \( \) i o n
```

## Dictionary compression for Reuters: Summary

| data structure                        | size in MB |
|---------------------------------------|------------|
| dictionary, fixed-width               | 11.2       |
| dictionary, term pointers into string | 7.6        |
| $\sim$ , with blocking, k = 4         | 7.1        |
| $\sim$ , with blocking & front coding | 5.9        |

#### Postings compression

- The postings file is much larger than the dictionary, factor of at least 10.
- Key desideratum: store each posting compactly
- A posting for our purposes is a docID.
- For Reuters (800,000 documents), we would use 32 bits per docID when using 4-byte integers.
- Alternatively, we can use log<sub>2</sub> 800,000 ≈ 19.6 < 20 bits per docID.
- Our goal: use a lot less than 20 bits per docID.

## Key idea: Store gaps instead of docIDs

- Each postings list is ordered in increasing order of docID.
- Example postings list: COMPUTER: 283154, 283159, 283202, . . .
- It suffices to store gaps: 283159-283154=5, 283202-283154=43
- Example postings list using gaps : COMPUTER: 283154, 5, 43, . . .
- Gaps for frequent terms are small.
- Thus: We can encode small gaps with fewer than 20 bits.

# Gap encoding

|                | encoding | postings | list   |        |     |        |   |        |    |        |  |
|----------------|----------|----------|--------|--------|-----|--------|---|--------|----|--------|--|
| THE            | docIDs   |          |        | 283042 |     | 283043 |   | 283044 |    | 283045 |  |
|                | gaps     |          |        |        | 1   |        | 1 |        | 1  |        |  |
| COMPUTER       | docIDs   |          |        | 283047 |     | 283154 |   | 283159 |    | 283202 |  |
|                | gaps     |          |        |        | 107 |        | 5 |        | 43 |        |  |
| ARACHNOCENTRIC | docIDs   | 252000   |        | 500100 |     |        |   |        |    |        |  |
|                | gaps     | 252000   | 248100 |        |     |        |   |        |    |        |  |

## Variable length encoding

#### Aim:

- For ARACHNOCENTRIC and other rare terms, we will use about 20 bits per gap (= posting).
- For THE and other very frequent terms, we will use only a few bits per gap (= posting).
- In order to implement this, we need to devise some form of variable length encoding.
- Variable length encoding uses few bits for small gaps and many bits for large gaps.

## Variable byte (VB) code

- Used by many commercial/research systems
- Good low-tech blend of variable-length coding and sensitivity to alignment matches (bit-level codes, see later).
- Dedicate 1 bit (high bit) to be a continuation bit c.
- If the gap G fits within 7 bits, binary-encode it in the 7 available bits and set c = 1.
- Else: encode lower-order 7 bits and then use one or more additional bytes to encode the higher order bits using the same algorithm.
- At the end set the continuation bit of the last byte to 1 (c = 1) and of the other bytes to 0 (c = 0).

# VB code examples

| docIDs  | 824               | 829      | 215406                     |
|---------|-------------------|----------|----------------------------|
| gaps    |                   | 5        | 214577                     |
| VB code | 00000110 10111000 | 10000101 | 00001101 00001100 10110001 |

## VB code encoding algorithm

```
VBENCODENUMBER(n)
                                            VBEncode(numbers)
    bytes \leftarrow \langle \rangle
                                                bytestream \leftarrow \langle \rangle
    while true
                                                for each n \in numbers
    do Prepend(bytes, n mod 128)
                                                do bytes \leftarrow VBENCODENUMBER(n)
        if n < 128
                                                     bytestream \leftarrow Extend(bytestream, bytes)
4
           then Break
                                                 return bytestream
        n \leftarrow n \text{ div } 128
    bytes[Length(bytes)] += 128
    return bytes
```

## VB code decoding algorithm

```
VBDecode(bytestream)
     numbers \leftarrow \langle \rangle
 2 \quad n \leftarrow 0
    for i \leftarrow 1 to Length(bytestream)
     do if bytestream[i] < 128
 5
            then n \leftarrow 128 \times n + bytestream[i]
            else n \leftarrow 128 \times n + (bytestream[i] - 128)
 6
                    Append(numbers, n)
 8
                    n \leftarrow 0
 9
     return numbers
```

## Gamma codes for gap encoding

- You can get even more compression with another type of variable length encoding: bitlevel code.
- Gamma code is the best known of these.
- First, we need unary code to be able to introduce gamma code.
- Unary code
  - Represent n as n 1s with a final 0.
  - Unary code for 3 is 1110

  - Unary code for 70 is:

#### Gamma code

- Represent a gap G as a pair of length and offset.
- Offset is the gap in binary, with the leading bit chopped off.
- For example  $13 \rightarrow 1101 \rightarrow 101 = offset$
- Length is the length of offset.
- For 13 (offset 101), the length is 3.
- Encode length in unary code: 1110.
- Gamma code of 13 is the concatenation of length and offset: 1110101.

## Gamma code examples

| number | unary code | length      | offset    | $\gamma$ code          |
|--------|------------|-------------|-----------|------------------------|
| 0      | 0          |             |           |                        |
| 1      | 10         | 0           |           | 0                      |
| 2      | 110        | 10          | 0         | 10,0                   |
| 3      | 1110       | 10          | 1         | 10,1                   |
| 4      | 11110      | 110         | 00        | 110,00                 |
| 9      | 1111111110 | 1110        | 001       | 1110,001               |
| 13     |            | 1110        | 101       | 1110,101               |
| 24     |            | 11110       | 1000      | 11110,1000             |
| 511    |            | 111111110   | 11111111  | 111111110,11111111     |
| 1025   |            | 11111111110 | 000000001 | 11111111110,0000000001 |

## Properties of gamma code

- Gamma code is prefix-free
- The length of offset is [log<sub>2</sub> G] bits.
- The length of length is  $\lfloor \log_2 G \rfloor + 1$  bits,
- So the length of the entire code is  $2 \times \lfloor \log_2 G \rfloor + 1$  bits.
- Υ codes are always of odd length.
- Gamma codes are within a factor of 2 of the optimal encoding length log<sub>2</sub> G.

## Gamma codes: Alignment

- Machines have word boundaries 8, 16, 32 bits
- Compressing and manipulating at granularity of bits can be slow.
- Variable byte encoding is aligned and thus potentially more efficient.
- Regardless of efficiency, variable byte is conceptually simpler at little additional space cost.

# **Compression of Reuters**

| data structure                         | size in MB |
|--|------------|
